

Service Manager App - One-Page Summary

What it is

Saudi Service Manager is a Flutter app for tracking service work orders and office operations with role-based views.

It uses Supabase for authentication, data storage, and role policies.

Who it's for

Primary persona: operations leaders and service staff in a multi-office service organization (roles in repo: super_admin, admin, staff).

What it does

- Auth flow with sign in/sign up and profile-driven role routing.
- Role-specific dashboards (executive/admin/staff) for different workflows.
- Work order lifecycle: create, assign, filter, update status, and timeline history.
- Attendance tracking with check-in/check-out sessions and daily/history monitoring.
- Leave management: staff requests plus admin approval/rejection workflow.
- Payments tracking per work order with paid/advance/pending state handling.
- Bilingual localization support (English/Arabic) with in-app language switch.

How it works

- UI layer: Flutter screens/widgets in feature modules (auth, dashboard, attendance, leaves, onboarding).
- State layer: Riverpod providers compose async data for screens and filtering.
- Data layer: repositories call Supabase tables (work_orders, profiles, attendance, leaves, payments, task_history, offices).
- Auth/authorization: Supabase Auth + profile role; SQL schema defines RLS policies by role.
- Data flow: user action -> provider/notifier -> repository -> Supabase -> provider refresh -> UI updates.

How to run

1. Prereq: Flutter SDK version requirement in repo is Dart ^3.8.1 (SDK install steps: Not found in repo).
2. From project root, run: flutter pub get
3. Launch app: flutter run
4. Backend setup commands/scripts are present as SQL files; exact environment provisioning steps are Not found in repo.
